Grain definitions

Phase 1 design deliverable v2 | 10 November 2026

Purpose

Each fact or bridge has one explicit row meaning. Grain protects counts from duplication during multi-source and many-to-many joins.

Requirements / design

research_output: one canonical logical output; source_record: one source-native record; output_version: one observed/versioned representation; output_relationship: one directed typed relation; output_observation: one canonical output per successful observation run; bridge_output_topic/creator/institution/funder: one output-member assignment; fact_publication_activity: one admitted output under a declared counting definition.

Scope and caveats

Final physical keys, dimensions, slowly-changing policy, and constraint definitions require review before Phase 2; do not treat this as executable schema.

Source and architecture references

See docs/sources.md, docs/architecture/README.md, docs/requirements/incremental-ingestion-design.md, docs/requirements/course-requirements-matrix.md, and the target architecture diagram. Phase 2 and Phase 3 implementation has not started.
